㉒ Digital data processing system.

㉓ A digitally coded signal is encoded with an error correction code and an error detection code. When the signal is decoded, the error correction code is used to correct errors. The error detection code is then used to discriminate whether the error correc-

tion process has operated properly, and if it has not operated properly then interpolation is used to avoid remaining errors. Preferably when the data is encoded the error detection code is provided before the error correction code is provided.

FIG. 3(b)

EP 0 461 787 A2

BACKGROUND OF THE INVENTIONField of the Invention

This invention relates to a digital processing system. The present invention may be applied to a digital recording and/or reproducing system. An aspect of the invention relates to the error compensating ability of such a system.

Related Background of Art

In recent years, digital recording and/or reproducing devices such as so called digital VTR have become widely used. One kind of digital VTR records segments by a method in which information for one TV frame is divided into several segments and these segments are recorded separately on several recording tracks of magnetic tape.

Fig 2 shows an example of coded data for one such segment of TV frame information. In this example a double product coding which consists of an inner coding (n, m) and an outer coding (q, p) is executed. This kind of double product coding can be Read-Solomon coding.

When reproducing this coded data, it is decoded and errors contained in the data are corrected using the error correction code if this is possible and if it is not possible to correct errors using the error correction code but an error is nevertheless detected, a compensation such as interpolation is executed by using data from information for an adjacent frame or for the same frame. However, the error rate in a transmission system such as a digital VTR may vary over a wide range and if the error rate is very high, improper correction of the errors may be carried out.

Since the prior digital VTR compensates decoded data depending on the result of the error correction, if improper error correction is carried out as mentioned above then the compensation may not be carried out when it should be, or may be carried out incorrectly or inappropriately. This compensation failure may cause serious damage in the reproduced image on a TV screen. In particular a burst error tends to occur for a relatively long period in a special effect reproducing mode of a VTR. So, unless the correction ability is greatly improved, a high quality image in special effect reproduction cannot be obtained.

SUMMARY OF THE INVENTION

An object of the present invention is to provide a digital data processing system which can resolve the above-mentioned problems.

Another object of the present invention is to

provide a recording and/or reproducing system having a high quality image without a great amount of error correction codes.

Still another object of the present invention is

5 to provide a recording and/or reproducing system that can reduce false error correction or false error compensation.

In one aspect of the present invention, a 10 digitally coded signal is encoded with an error correction code and an error detection code. When the signal is decoded, the error correction code is used to correct errors. The error detection code is then used to discriminate whether the error correction process has operated properly, and if it has 15 not operated properly then compensation such as interpolation is used to avoid remaining errors.

In order to achieve the above-mentioned 20 object, an aspect of the present invention provides a digital data processing system, comprising receiving means for receiving a digital coded signal which contains an error detection code and an error correction code, decoding means for decoding said digital coded signal and for generating an 25 indication signal when an error is detected by using said error detection code, and compensating means for compensating an output of said decoding means, characterised in that said compensating means compensates an output of said decoding means when said indication is generated.

30 Accordingly compensation will normally be carried out correctly even if there is improper error correcting, and the added code length in total is less than the added code length which the prior art would need for obtaining the same error compensation ability.

BRIEF DESCRIPTION OF THE DRAWINGS

40 FIG. 1A illustrates a block diagram of recording system of an embodiment of the present invention.

FIG. 1B illustrates a block diagram of reproducing system of an embodiment of the present invention.

45 FIG. 2A and 2B illustrate a coded data format of prior art.

FIG. 3A and 3B illustrate a coded data format of an embodiment of the present invention.

DETAILED DESCRIPTION OF THE PRESENT EMBODIMENTS

55 An embodiment of the present invention, given by way of non-limiting example, will now be described with reference to the drawings.

FIGS. 1A and 1B respectively illustrate a recording and a reproducing block diagram of a digital VTR. An analog video signal input through

an input terminal 10 is converted into an 8-bit digital video signal by an analog to digital converter 12.

The 8-bit digital video signal is supplied to a filter 14, where the digital video signal is sub-sampled and then filtered to cut off noise components caused by the sub-sampling.

The filtered digital video signal is encoded as shown in Figure 3.

Figure 3(a) shows one segment of the coded video data. The segment comprises a sync data portion 51, an ID data portion 52, a CRCC portion 53 for the ID data, a first video data portion 54, which is m bytes long, a first inner parity code section 55 for the first video data portion 54, a second video data portion 56, which is $(m-2)$ bytes long, a CRCC portion 57 for the video data of both portions 54, 56, which CRCC portion 57 is 2 bytes long, and a second inner parity code portion 58 for the combination of the second video data portion 56 and the CRCC portion 57. The first video data portion 54 and the first inner parity code portion 55 jointly comprise n bytes, and the second video data portion 56, the CRCC portion 57 and the second inner parity code portion 58 jointly comprise n bytes.

Figure 3(b) shows a block of data, made up of q segments. Of the q segments in Figure 3(b) the first p segments are as shown in Figure 3(a) and the remaining segment or segments have outer parity codes 59,60 in place of the video data portions 54,56 and the CRCC portion 57.

The filtered digital video signal is supplied to an error detection coding circuit 16, where an error detection code such as CRCC (Cyclic Redundancy Check Code) is added to the signal. In this embodiment the error detection code has two bytes and is provided for each segment, which includes $(2m-2)$ bytes of video data as shown in Figure 3(a).

An error correction coding circuit 18 codes the video data to which the error detection code had been added by circuit 16 in the order of outer coding (q, p coding, provided by outer parity codes 59,60) and then inner coding (n, m coding, provided by the inner parity code portions 55,58) according to, for example, a Read-Solomon coding method.

A sync and ID adding circuit 20 adds sync block data which consists of sync data 51, ID data 52 and a CRCC 53 for the ID data to the signal output by the error correction coding circuit 18.

A recording block 22 has a function as a transmitter and modulates the signal output by the sync and ID adding circuit 20 to record it on a recording medium.

In the embodiment of Figure 1A, the error detection coding circuit 16 operates on the digital data before the error correction coding circuit 18,

so that the error detection code is already present in the data when the error correction code is added. This arrangement is preferred to the reverse arrangement of error correction coding and then error detection coding.

In FIG. 1B a reproducing block 24 has a function as a receiver and picks up the recorded data on the recording medium and demodulates it. A sync and ID detection circuit 26 detects the sync data and the ID data and checks and corrects the ID data by using the CRCC for the ID data.

An error correction decoding circuit 28 corrects any errors in an output of the circuit 26 caused during recording and reproducing so far as possible by repeatedly decoding it using the inner parity coding data 55,58 and the outer parity coding data 59,60 according to a predetermined algorithm. Error corrected data is then supplied to an error detection decoding circuit 30.

The circuit 30 uses the CRCC portion 57 for the video data to detect any remaining error in the error corrected data. The circuit 30 outputs the video data through a line 30a and a flag signal through a line 30b, where the flag signal is "1" when an error is detected and "0" when an error is not detected by the error detection circuit 30.

An interpolation circuit 32 receives the flag signal and the video signal, and executes interpolation when the flag signal is "1". The output of the interpolation circuit 32 is supplied to an image memory 34 and is stored in an address designated by the ID data 52.

The interpolation by the interpolation circuit 32 is executed by using the adjacent upper and/or lower line of video signal or using the same line of video signal of an adjacent frame signal or by any other suitable method. If the interpolation is executed by using the same line of video signal of an adjacent frame signal, it can be carried out simply by not overwriting the pre-existing content of the image memory 34.

The data stored in the image memory 34 is read out sequentially and is supplied to a high frequency restoring circuit 36 which produces a high frequency component by, for example, interpolation.

The output of the restoring circuit 36 is then supplied to a digital to analog converter and is converted into analog signal, and is then output from an output terminal 40.

In the special effect reproduction mode such as a search mode of VTR, valid data may only be available intermittently. By storing the data in the image memory 34 only when the flag signal is "0", a high quality reproduced image can be obtained.

Claims

1. A digital data processing system for receiving and decoding digital data which has been encoded using both an error correction code and an error detection code, the system using the error correction code to correct errors in the received data and the error detection code to detect errors, characterised in that:

the error detection code is used to detect errors present in the received data after error correction using the error correction code, and if such errors are found further action, such as interpolation, is taken to compensate for such errors even if errors have been corrected using the error correction code.

2. A method of processing a received digital data signal which has been encoded using both an error correction code and an error detection code, the method comprising the steps of:

- i) using the error correction code to correct errors in the received signal if this is required and is possible, and
- ii) using the error detection code to detect errors,

characterised in that:

the error detection code is used to detect errors present in the received signal after error correction, and in that the method comprises the step of:

- iii) compensating for errors which are detected to be present in the received signal after errors in it have been corrected in the said error correction step.

3. A digital data processing system comprising:
 - a) receiving means (24) for receiving a digital coded signal which contains an error detection code and an error correction code;
 - b) decoding means (30) for decoding said digital coded signal and for generating an indication signal (30b) when an error is detected by using said error detection code;
 - c) compensating means (32) for compensating an output (30a) of said decoding means (30), characterised in that said compensating means (32) compensates the said output (30a) of said decoding means (30) when said indication (30b) is generated.

4. A system according to claim 3, wherein said receiving means (24) comprises reproducing means for reproducing said digital coded signal from a recording medium.

5. A system according to claim 3, further comprising:
 - error detection coding means for coding a

digital signal so as to contain an error detection code.

6. A system according to claim 5, further comprising:

error correction coding means for coding the digital signal containing the error detection code so as to contain an error correction code.

7. A system according to claim 6, further comprising:

transmission means for transmitting an output of said error correction coding means.

8. A system according to claim 7, wherein said transmission means comprises recording means for recording said output to a recording medium.

9. A digital data processing method or apparatus in which compensation for detected errors is carried out in response to the detection of errors even if an error correction step has already been carried out.

10. A digital processing system for encoding digital data, the system encoding received digital data with an error detection code and further encoding the coded digital data with an error correction code.

11. A method of encoding digital data in which the digital data is encoded with both an error correction code and an error detection code, characterised in that:

the digital data is encoded with the error detection code, and afterwards the digital data is encoded with the error correction code.

12. A digital data processing device comprising:

a) error detection coding means for coding a digital signal so as to contain an error detection code;

- b) error correction coding means for coding the digital signal containing the error detection code so as to contain an error correction code; and

c) transmission means for transmitting an output of said error correction coding means.

13. A system according to any one of claims 1, 3 to 8, 10 and 12 or a method according to claim 2 or claim 11, wherein said error detection code comprises a CRCC.

14. A system according to any one of claims 1, 3 to 8, 10, 12 and 13 or a method according to

any one of claims 2, 11 and 13, wherein said error correction code comprises an inner code and an outer code.

15. A system according to any one of claims 1, 3 to 8, 10 and 12 to 14 or a method according to any one of claims 2, 11, 13 and 14, wherein said error correction code comprises a Read-Solomon code.
